Continuous recording script and screen guide

14 slides | 6:30 raw | about 4:49 at 1.35x | 772 spoken words

Main question: What do averages and snapshots hide about inequality, relationships and change over time?

Scenes 2-3 replace the old network examples. All 15,931 pairs are scored; P95 = 0.569763 retains 797 edges. Twelve isolated countries remain. Group 5 now has 15 countries and 93 of 105 retained pairs. Use this guide with the updated final PowerPoint.

01 0:00-0:10 Parikshith: What does the summary leave out?

02 0:10-0:35 Parikshith: Similarity needs a visible threshold

03 0:35-1:05 Parikshith: Groups still contain unequal relationships

04 1:05-1:35 Varshith: Does high internet use mean high fixed broadband?

05 1:35-2:10 Varshith: Six countries break the simple expectation

06 2:10-2:50 Sindhoor: Progress does not mean everyone caught up

07 2:50-3:15 Sindhoor: Internet: three findings, one answer

08 3:15-3:45 Parikshith: Weather: can the same colour mislead us?

09 3:45-4:20 Parikshith: A monthly total cannot tell us when rain fell

10 4:20-4:45 Sindhoor: Contours let us follow temperature boundaries

11 4:45-5:25 Sindhoor: How often and how long are different questions

12 5:25-6:00 Varshith: Arrow length changes the pattern we notice

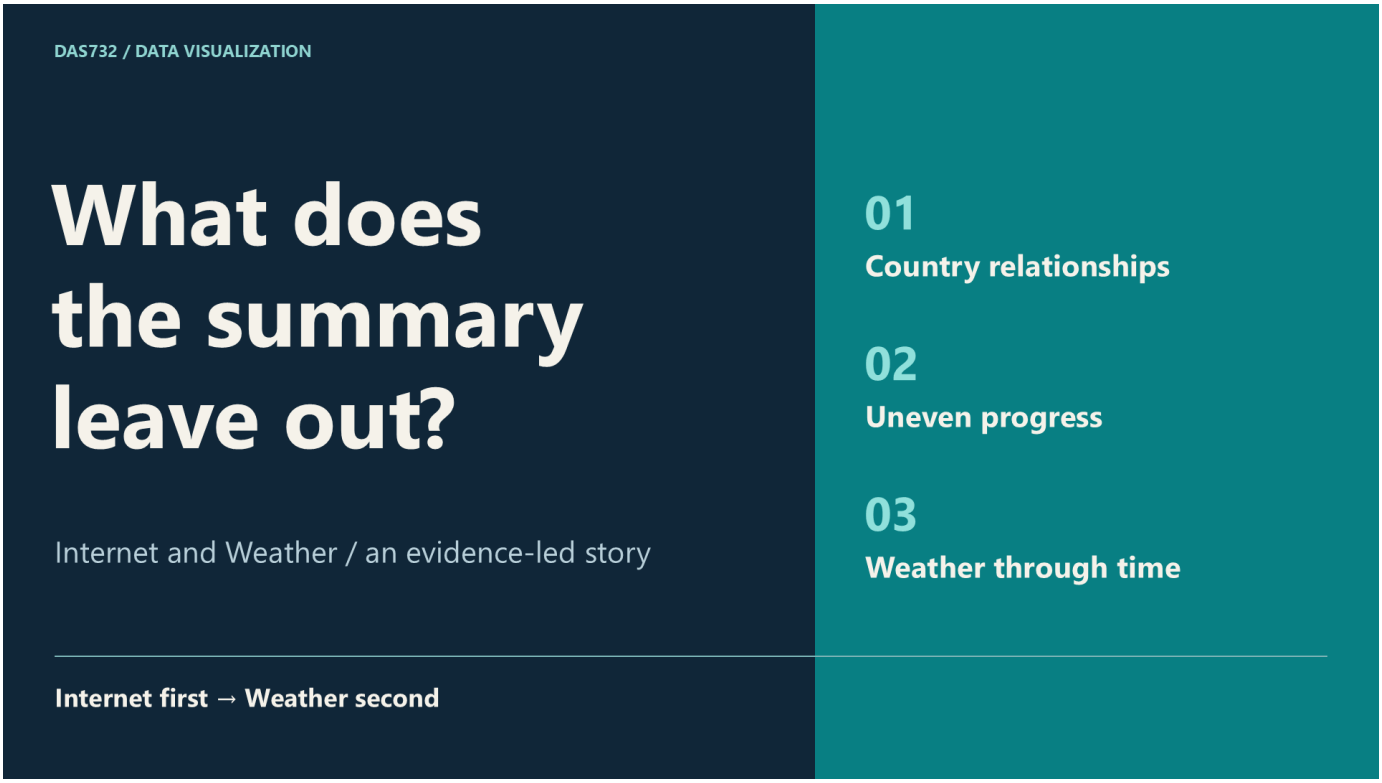

13 6:00-6:24 Varshith: What do averages and snapshots leave out?

14 6:24-6:30 Silent closing card: Team Plot Twist

Record the actions as well as the speech. Play the GIFs on slides 8 and 10; record the real browser brush on slides 4-5. The full network demo can show default, complete graph at zero, and reset. Raw times remain unchanged. Use pitch preservation when accelerating the final recording.

01. What does the summary leave out?

Parikshith | 0:00-0:10 raw (10 seconds)

SAY

What do averages and snapshots leave out? We examine Internet first, then Weather, following the evidence to a conclusion.

SHOW / ACTIONS

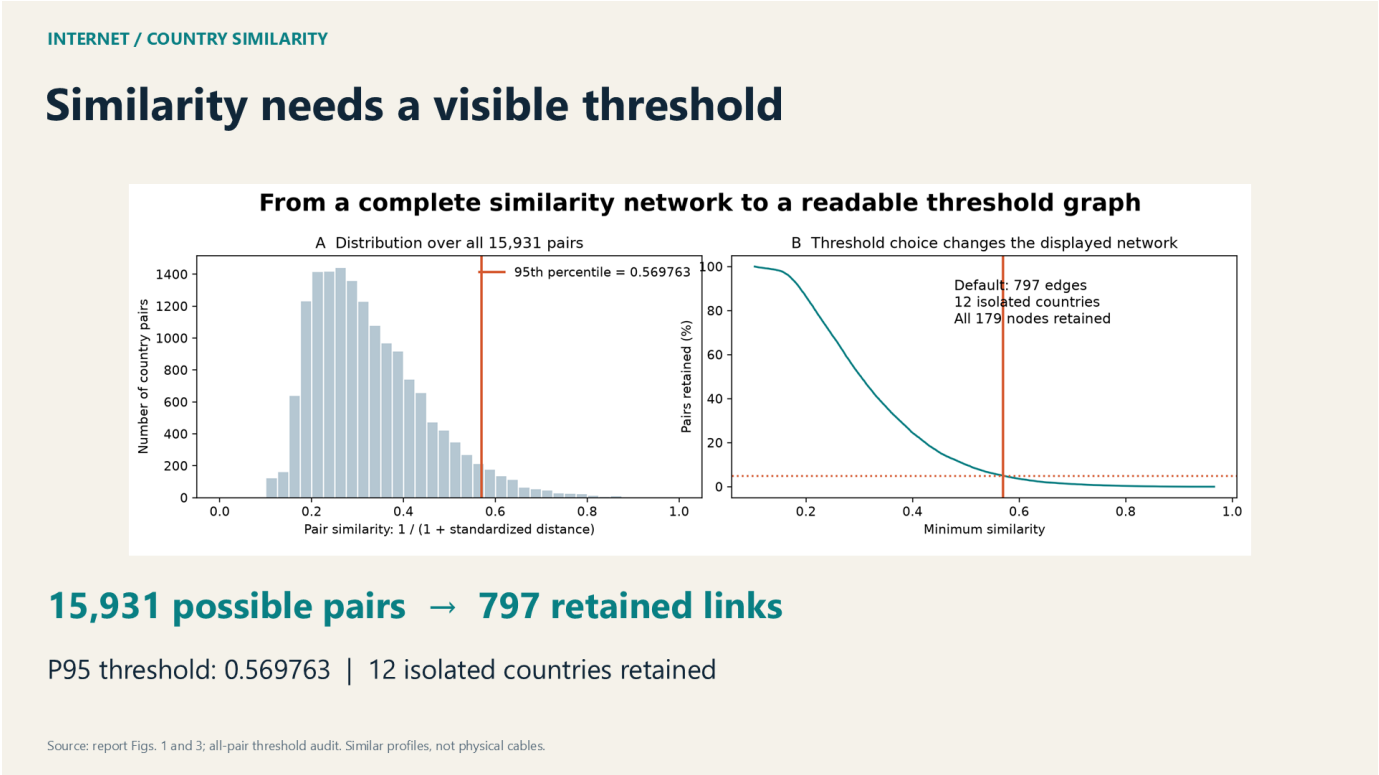

State the main question. Explain that Internet finishes before Weather starts. Do not list every method.

Main point: Look inside groups. Follow the measurements. Check time.

Source: Current report: question and conclusions

02. Similarity needs a visible threshold

Parikshith | 0:10-0:35 raw (25 seconds)

SAY

Madam confirmed that similarity networks are suitable. We now score all fifteen thousand nine hundred and thirty-one country pairs. This histogram shows their similarities. Our declared ninety-fifth-percentile threshold keeps seven hundred and ninety-seven links. Twelve countries have no pair above it, but remain in the data. The browser can show every pair or change the threshold.

SHOW / ACTIONS

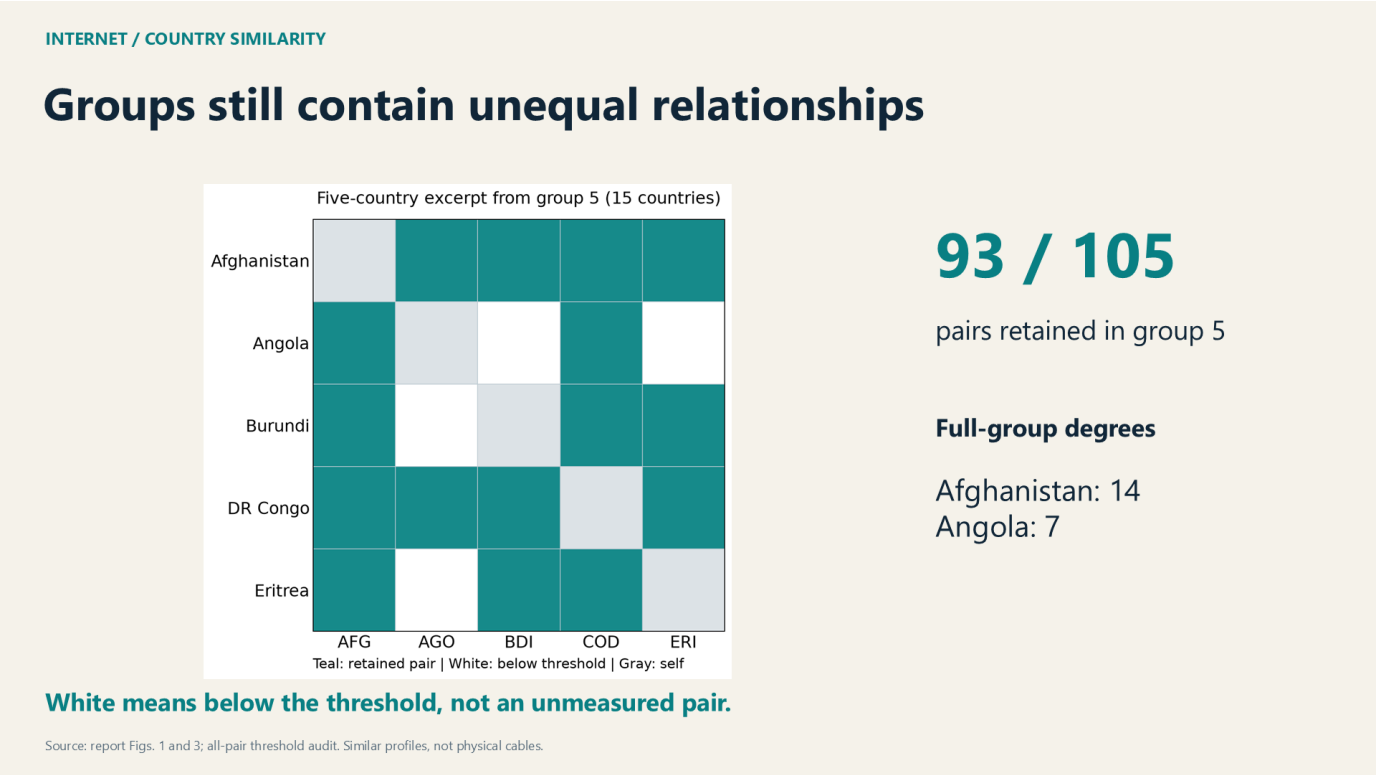

Point to the histogram and cutoff. State that the top five percent is a transparent starting view, not an optimal or significant threshold. Keep the retained-edge count and isolated-node count visible.

Main point: A visible threshold makes the filtered network interpretable.

Source: Updated report Figure 1; data/network_threshold_audit.json; all-pair scores.

03. Groups still contain unequal relationships

Parikshith | 0:35-1:05 raw (30 seconds)

SAY

NodeTrix now uses the filtered graph. Group five retains ninety-three of its one hundred and five possible pairs. This excerpt shows five of its fifteen countries. Afghanistan has fourteen links within the full group, while Angola has seven. Teal means above our similarity threshold; white means below it. A shared group label still hides different relationships. These links describe profiles, not physical cables.

SHOW / ACTIONS

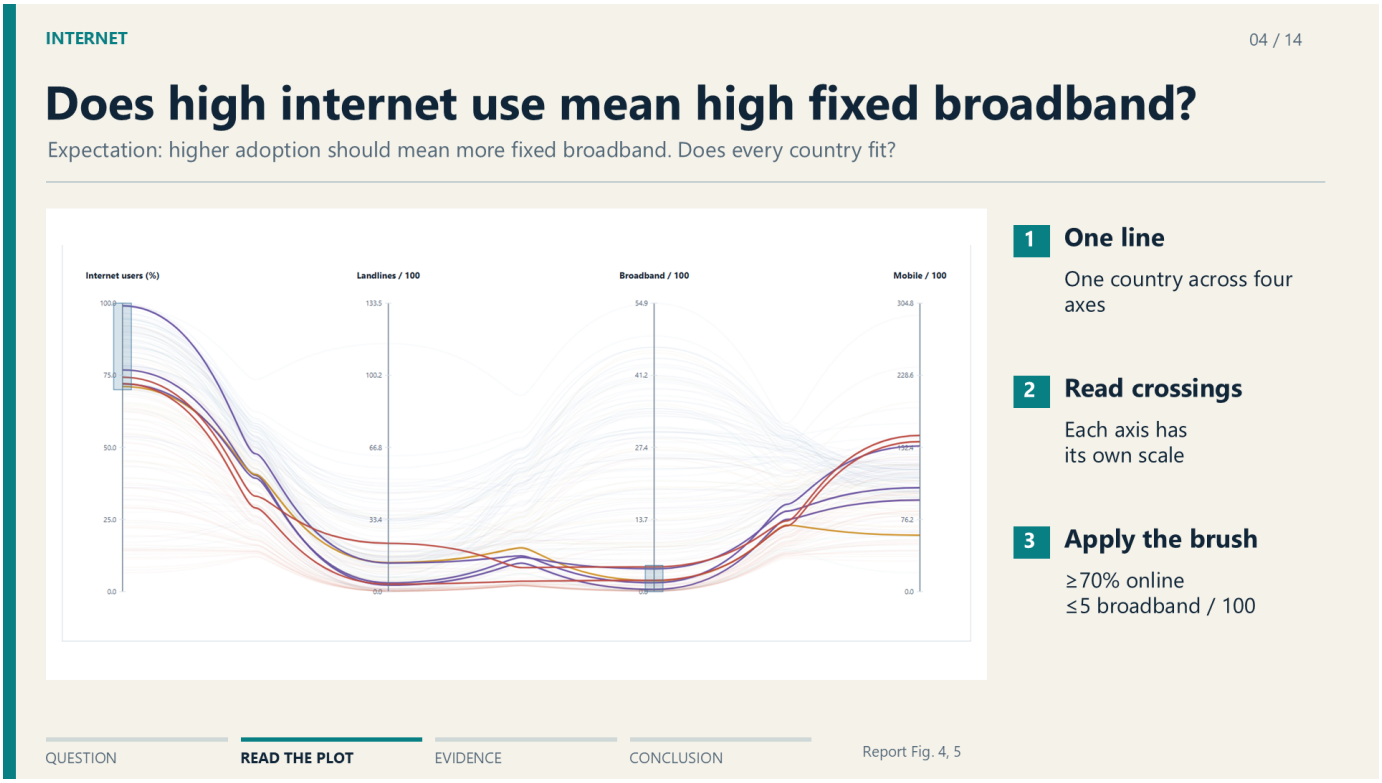

Read the five-country excerpt. Compare Afghanistan and Angola; state that 14 and 7 are degrees in the full 15-country group, not only in this excerpt. Explain the Angola-Burundi white cell. Do not count excerpt cells as the full 93 edges.

Main point: White means below the threshold; a shared group label still hides differences.

Source: Updated report Figure 3; output/network_revision/nodetrix_detail_matrix.csv and facts.json.

04. Does high internet use mean high fixed broadband?

Varshith | 1:05-1:35 raw (30 seconds)

SAY

Does high internet use always come with high fixed broadband? One line follows the same country across four measurements. Each axis has its own scale. Read where the line crosses an axis, not the bend between axes. Faint lines keep the other countries visible. I select at least seventy percent internet use and at most five fixed-broadband subscriptions per hundred people.

SHOW / ACTIONS

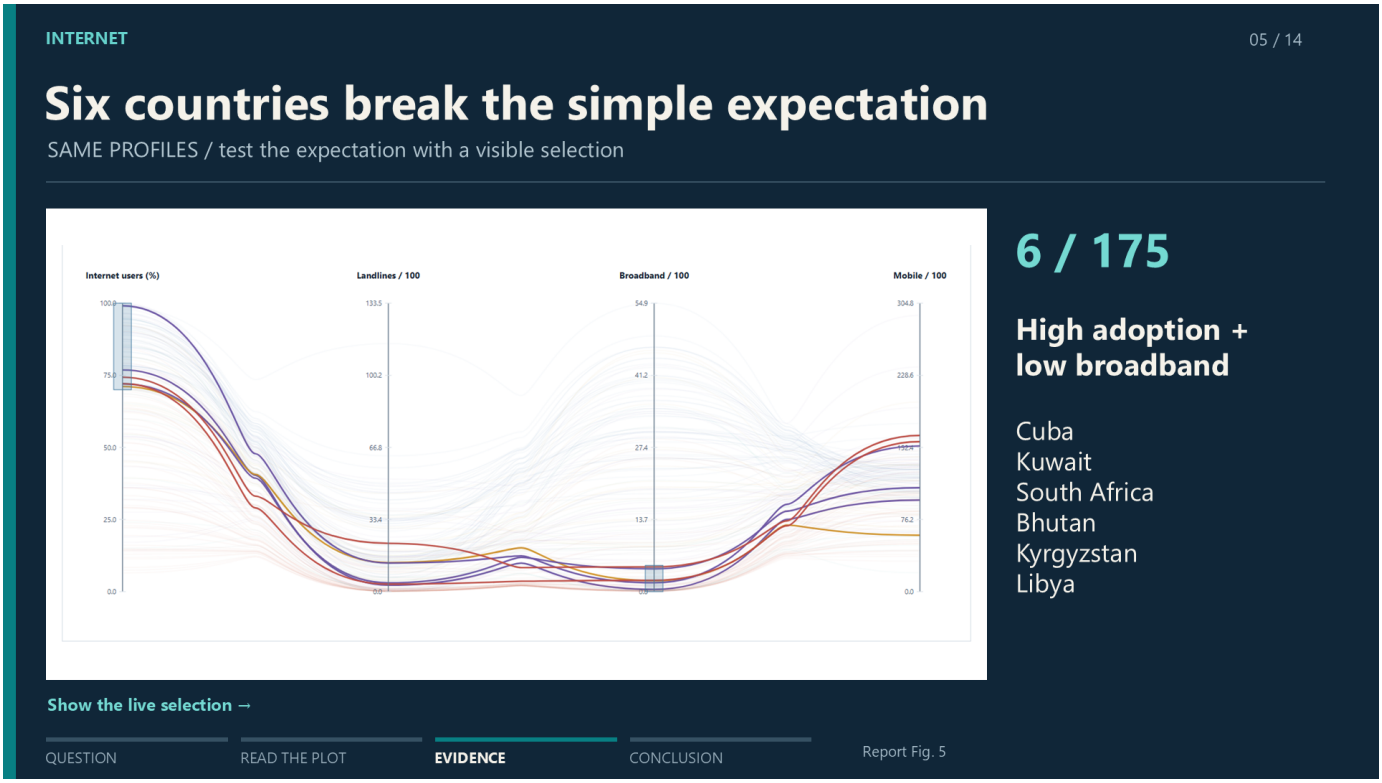

Show the four axes, then point at the two brush ranges. On the live browser page, apply Inspect high adoption / low broadband. Focus on one selected line; do not demonstrate unrelated controls yet.

Main point: Follow one country across all four axes.

Source: Report Fig. 4, 5

05. Six countries break the simple expectation

Varshith | 1:35-2:10 raw (35 seconds)

SAY

Six of the one hundred and seventy-five matched countries meet both conditions. Their lines start high on internet use and cross low on fixed broadband. Cuba, Kuwait and South Africa are among them. I change the brush, then restore it, to demonstrate the selection. Fixed broadband alone therefore does not describe internet access. We cannot tell from this plot which connection each person uses.

SHOW / ACTIONS

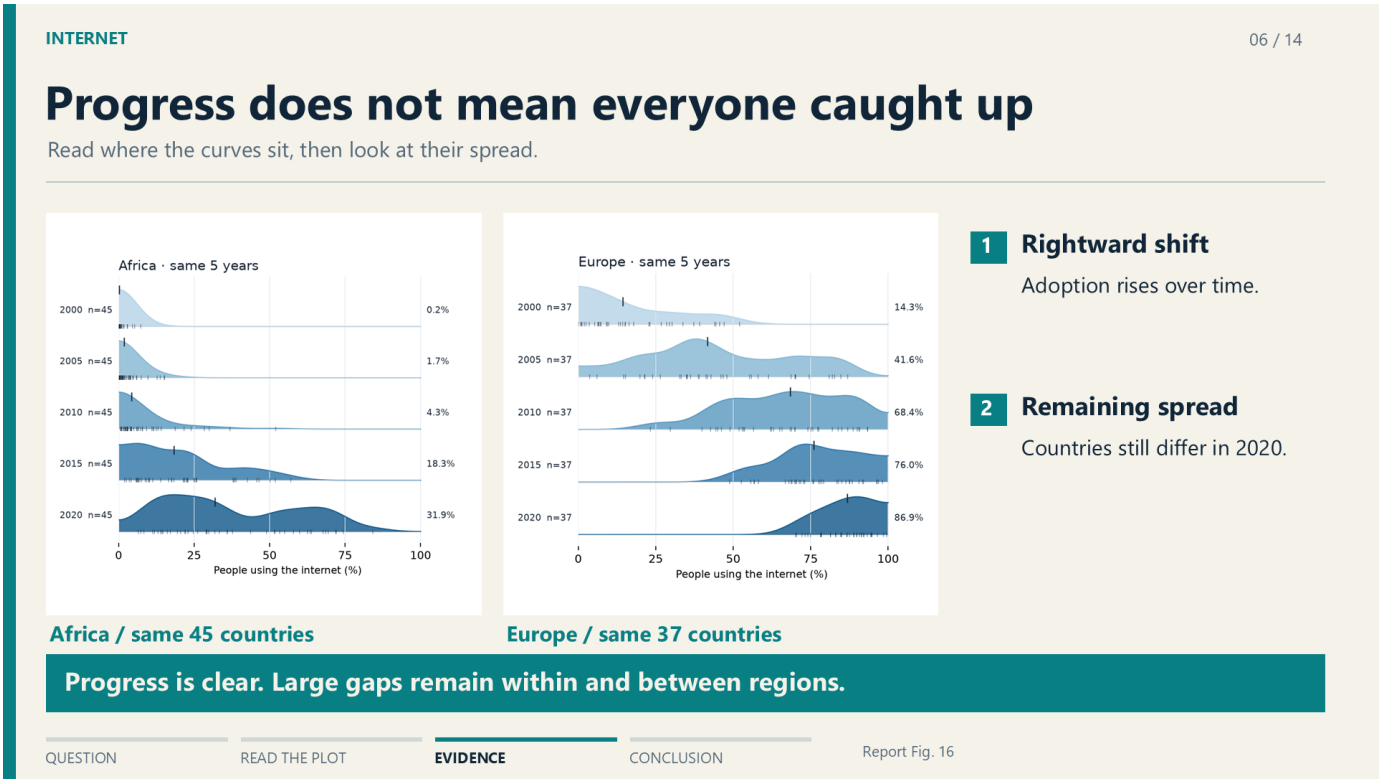

Record the real browser interaction from the slide link: apply the preset, move one brush slightly, then restore it. Keep six names and the 6-of-175 denominator visible. Return to the finding slide. Avoid a tour of every feature.

Main point: High adoption can exist with little fixed broadband.

Source: Report Fig. 5

06. Progress does not mean everyone caught up

Sindhoor | 2:10-2:50 raw (40 seconds)

SAY

Has progress closed the divide? These ridgelines follow the same countries at five dates. Moving right means higher internet use. Each curve shows the spread of countries; small ticks mark individual countries. Africa's median rises from about zero to thirty-two percent, but its final curve remains wide. Europe moves right and reaches a much higher median. Progress is clear, yet differences remain within and between regions. Curve height is not a count of people.

SHOW / ACTIONS

Read the 0–100 horizontal scale once. Trace Africa from 2000 to 2020; point at the wide final curve and the country ticks. Then compare Europe on the SAME scale. These are two labelled panels selected from report Fig. 16, not all regions.

Main point: Compare where the curves sit AND how widely they spread.

Source: Report Fig. 16

07. Internet: three findings, one answer

Sindhoor | 2:50-3:15 raw (25 seconds)

SAY

The internet evidence gives a connected answer. The matrix reveals different relationships inside one group. The selected profiles show high internet use with little fixed broadband. The ridgelines show progress with remaining gaps. A single adoption number cannot describe these differences. We need the relationships, other measurements and the spread of countries before saying the divide has closed.

SHOW / ACTIONS

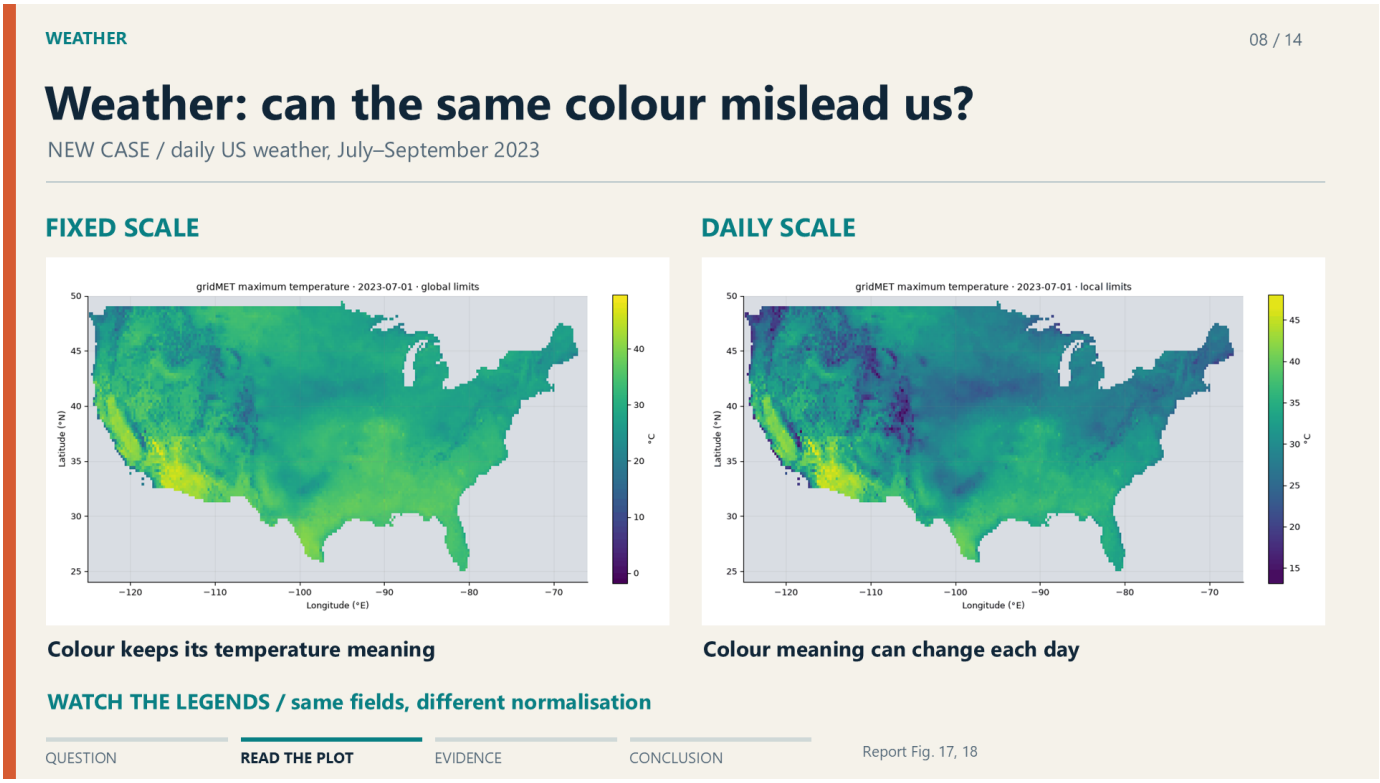

Use the three numbered evidence statements to recap the reasoning. Introduce no new figure. Pause before the Weather section.

Main point: A single adoption number cannot describe the whole connection profile.

Source: Report Fig. 3, 5, 16

08. Weather: can the same colour mislead us?

Parikshith | 3:15-3:45 raw (30 seconds)

SAY

We now move to ninety-two days of United States weather. These animations show the same temperature fields. The left legend stays fixed, so a colour keeps its temperature meaning across dates. The right legend resets each day. Local variation becomes clearer, but the same colour can mean a different temperature. Watch that changing legend. We use fixed scales to compare dates fairly.

SHOW / ACTIONS

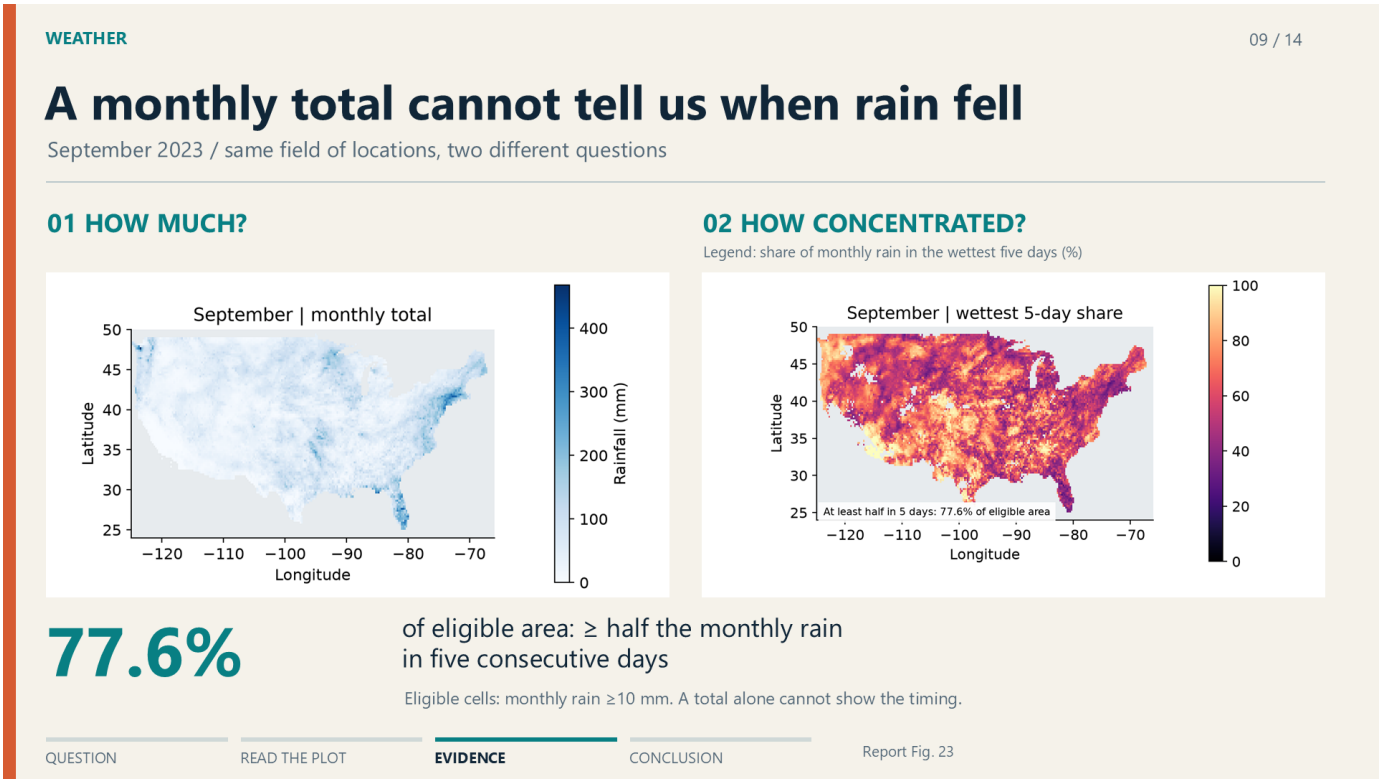

Stay in desktop PowerPoint Slide Show. Let both embedded GIFs complete at least two 6.4-second loops. Point to each colour bar; do not open another animation window.

Main point: Read the legend before comparing dates.

Source: Report Fig. 17, 18

09. A monthly total cannot tell us when rain fell

Parikshith | 3:45-4:20 raw (35 seconds)

SAY

The left map shows September rainfall totals. The right map asks when that rain fell: what share arrived in the wettest five consecutive days? Bright areas have strongly concentrated rain. Across seventy-seven point six percent of the eligible area, at least half the monthly rain fell within five days. A monthly total therefore hides whether rain arrived steadily or in short bursts. Daily observations recover that timing.

SHOW / ACTIONS

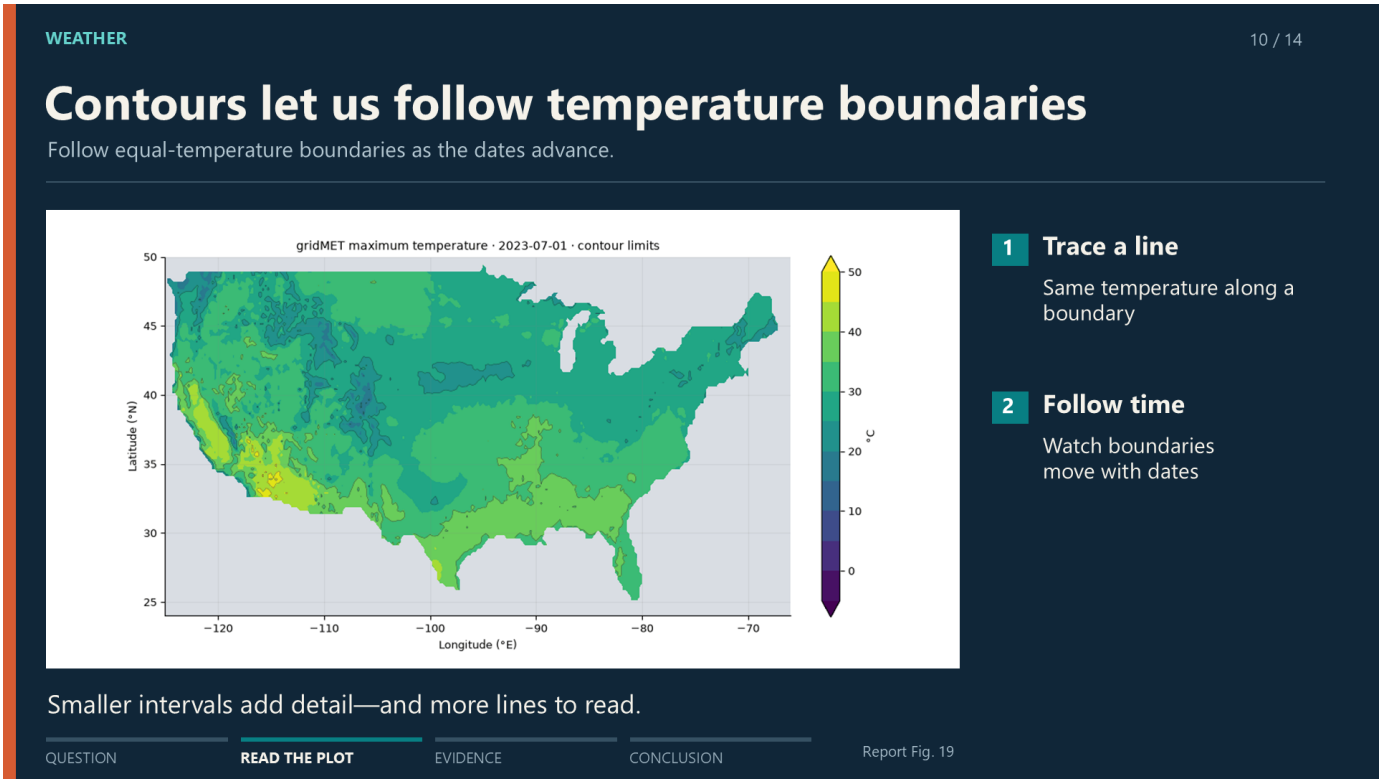

Read the monthly-total map on the left, then the wettest-five-day share on the right. Point to the 0–100% legend. State that 77.6% is eligible area, not a percentage of all rain. Eligible cells have September rainfall of at least 10 mm.

Main point: The same month needs both a total and a timing view.

Source: Report Fig. 23

10. Contours let us follow temperature boundaries

Sindhoor | 4:20-4:45 raw (25 seconds)

SAY

Each contour line follows equal temperature, while filled bands show ranges. As dates advance, we can follow those boundaries. Smaller intervals expose more detail but create more lines to read. We choose an interval that keeps the regional pattern visible. More detail is useful only when it helps answer the question.

SHOW / ACTIONS

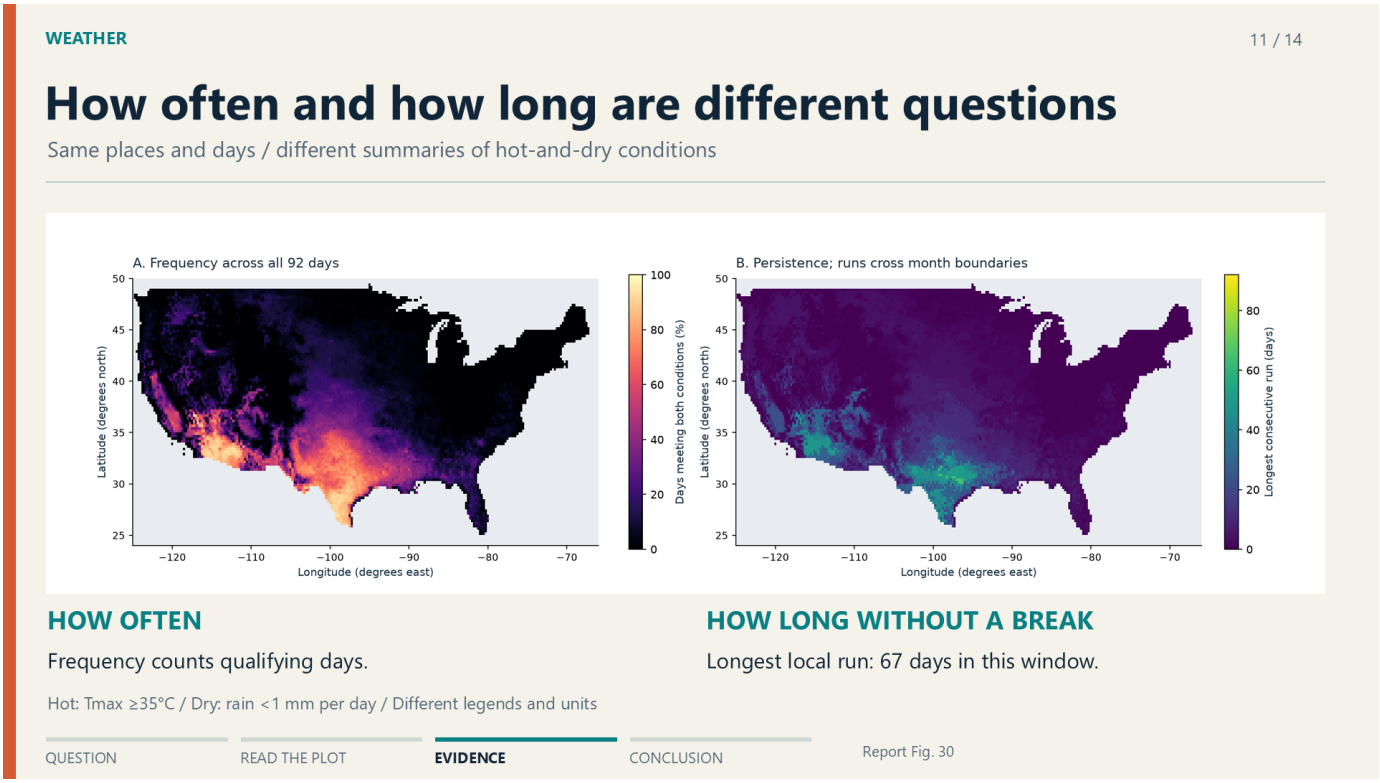

Let the embedded contour GIF complete two loops. Point to one boundary and its value on the legend. Explain why changing the interval changes detail; keep the same temperature field as the reference.

Main point: A contour follows equal temperature, not a state border.

Source: Report Fig. 19

11. How often and how long are different questions

Sindhoor | 4:45-5:25 raw (40 seconds)

SAY

The left map counts how often a place was both hot and dry. The right records its longest uninterrupted run. Hot means at least thirty-five degrees; dry means less than one millimetre of daily rain. Many qualifying days can be separated by breaks, so frequency cannot tell us persistence. The longest local run in this ninety-two-day window is sixty-seven days. Reading both maps separates repeated events from sustained conditions.

SHOW / ACTIONS

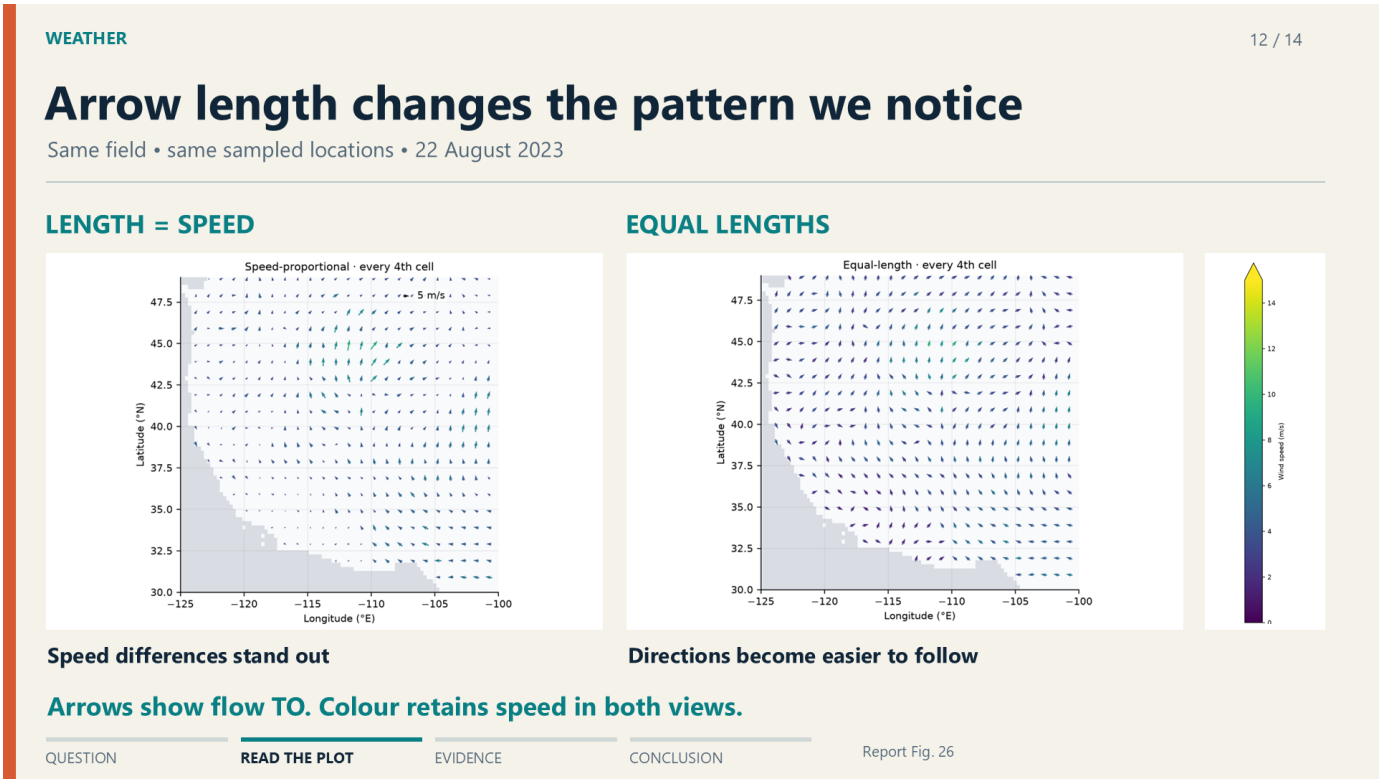

Read the left frequency legend and the right run-length legend separately. Point to the southwest pattern and compare the maps; do not equate their colours because the units differ. The 67-day maximum is somewhere in the grid and is bounded by the study window.

Main point: Frequent hot-and-dry days need not form one long spell.

Source: Report Fig. 30

12. Arrow length changes the pattern we notice

Varshith | 5:25-6:00 raw (35 seconds)

SAY

Both maps use the same wind field and sampled locations. On the left, arrow length grows with speed, so slow winds can be hard to follow. Equal lengths on the right make directions clearer; colour still shows speed. Arrows point where air moves, after converting the source wind-from direction. The measurements stay the same. We choose the view according to whether we need speed differences or direction patterns.

SHOW / ACTIONS

Compare the same western-US area in the two panels. Both retain every fourth sampled grid cell from the source experiment. Point first to short arrows and then to matching equal-length arrows. Use the retained common speed colour key.

Main point: Use length for speed; use equal lengths to inspect direction.

Source: Report Fig. 26

13. What do averages and snapshots leave out?

Varshith | 6:00-6:24 raw (24 seconds)

SAY

Our answer is that summaries leave out differences and time. For Internet, the group label and adoption number miss different country profiles and uneven progress. For Weather, monthly totals and event counts miss bursts and long uninterrupted spells. The strongest explanation therefore pairs the summary with the detail needed for the question, and draws its conclusion from that visible evidence.

SHOW / ACTIONS

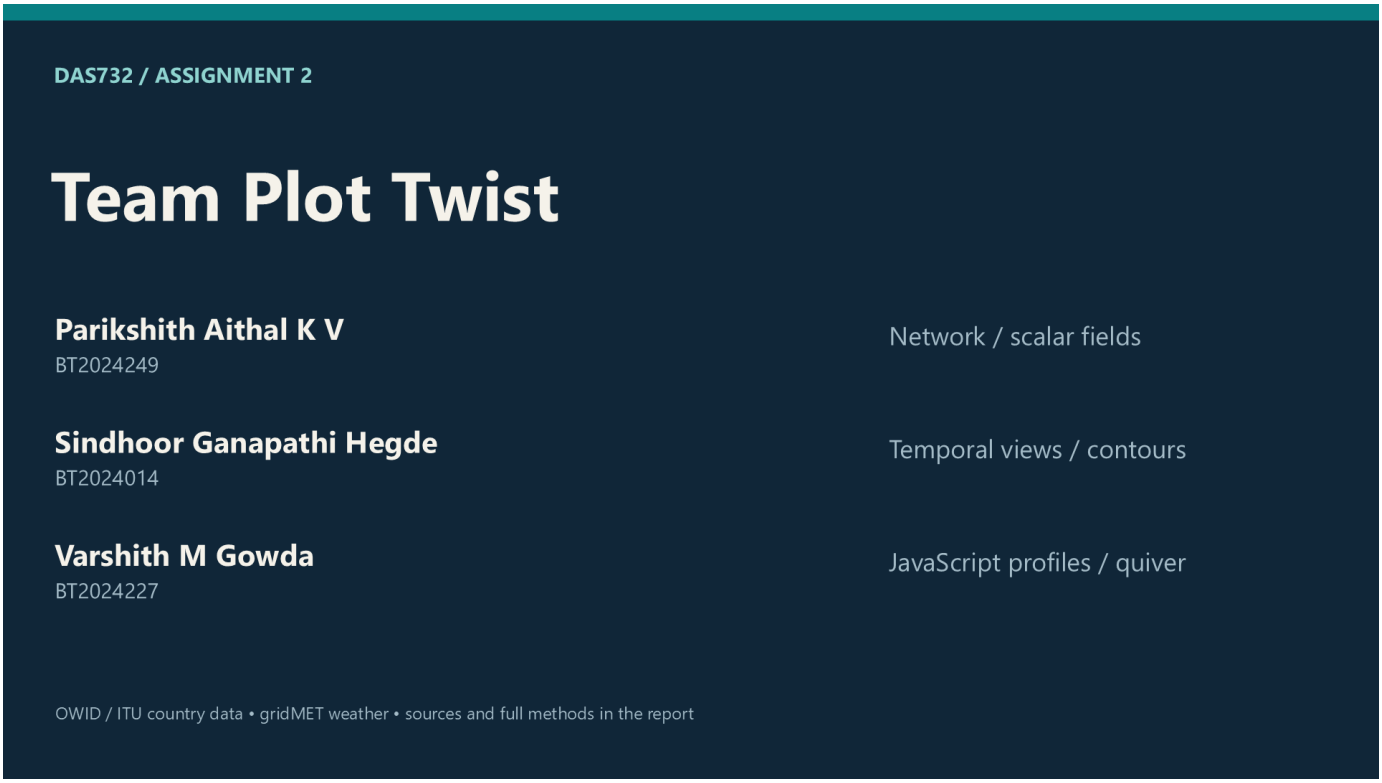

Connect each conclusion to the named evidence already shown. Introduce no new numbers or chart. Advance to credits after the final sentence.

Main point: Show the pattern, explain the evidence, state what follows.

Source: Report Fig. 3, 5, 16, 23, 30

14. Team Plot Twist

Silent closing card | 6:24-6:30 raw (6 seconds)

SAY

[Silent closing hold.]

SHOW / ACTIONS

Hold for six seconds. End recording.

Main point: Internet complete. Weather complete.

Source: Current report: question and conclusions
